SPECTRAL ASYMPTOTICS OF THE DIRICHLET LAPLACIAN IN A CONICAL LAYER
MONIQUE DAUGE, THOMAS OURMIÈRES-BONAFOSS, AND NICOLAS RAYMOND

ABSTRACT. The spectrum of the Dirichlet Laplacian on conical layers is analysed through two aspects: the infiniteness of the discrete eigenvalues and their expansions in the small aperture limit.

On the one hand, we prove that, for any aperture, the eigenvalues accumulate below the threshold of the essential spectrum: For a small distance from the essential spectrum, the number of eigenvalues farther from the threshold than this distance behaves like the logarithm of the distance.

On the other hand, in the small aperture regime, we provide a two-term asymptotics of the first eigenvalues thanks to a priori localization estimates for the associated eigenfunctions. We prove that these eigenfunctions are localized in the conical cap at a scale of order the cubic root of the aperture angle and that they get into the other part of the layer at a scale involving the logarithm of the aperture angle.

1. INTRODUCTION

1.1. Motivations. In mesoscopic physics semiconductors can be modelled by Schrödinger operators on tubes (also called waveguides) or layers carrying the Dirichlet condition on their boundaries. The existence of bound states for the Dirichlet Laplacian in such structures is an important issue since, in actual physical systems, the discrete spectrum will give rise to resonances.

First, the question of the discrete spectrum was studied for waveguides i.e. infinite tubes (in dimension two or three) which are asymptotically straight. For these tubes, one can prove that the essential spectrum of the Dirichlet Laplacian has the form \([a, +\infty)\) (with \(a \in \mathbb{R}_+\)). For smooth waveguides, the effect of bending is studied by Exner and Šeba in [15] and Goldstone and Jaffe in [18]. In [13], Duclos and Exner prove that bending induces bound states. The same question was addressed in dimension two when there is a corner (which can be seen as a point where the curvature gets unbounded). In [17], Exner, Šeba and Šťovíček prove that for the \(L\)-shaped waveguide there is a unique bound state below the threshold of the essential spectrum. Two of the authors, with Lafranche, prove in [10] that for a two dimensional waveguide with corner of arbitrary angle, the bound states are in finite number below the threshold of the essential spectrum. In fact, in [30], Nazarov and Shanin prove that for a large enough angle there is a unique bound state.

Second, the question was addressed for layers i.e. infinite regions in \(\mathbb{R}^3\) limited by two identical surfaces. For smooth enough layers, Duclos, Exner and Krejčiřík in [14] and then Carron, Exner and Krejčiřík in [7] prove that bending could induce bound states. Now, like for two dimensional waveguides, one can wonder what happens when there is a point where the curvature blows up. In
[16], Exner and Tater deal with this question in the particular case of a conical layer, i.e., a layer limited by two infinite coaxial conical surfaces with same openings. Again, the essential spectrum of the Dirichlet Laplacian has the form \([a, +\infty)\) (with \(a \in \mathbb{R}_+\)) and one of the main results of their paper is the infiniteness of the discrete spectrum below the threshold \(a\).

The first question we tackle in this paper is to quantify this infinity: As the two dimensional waveguide with corner in [10] is the meridian domain of the conical layer in [16], we wanted to understand how one can pass from a finite number of bound states to an infinite number adding one dimension. In the same spirit it is worth mentioning the paper [4] of Behrndt, Exner and Lotoreichik where the spectrum of the Dirichlet Laplacian with a \(\delta\)-interaction on a cone is investigated. Roughly, one can claim that this operator is another modeling of the physical phenomenon we are interested in. In this problem, the essential spectrum has the form \([-a, +\infty)\) (with \(a \in \mathbb{R}_+\)) and there is an infinite number of bound states. For \(n \geq 1\), they also provide an upper bound for the \(n\)-th eigenvalue of the problem.

The second question dealt with in the present paper is the study of the eigenvalues and associated eigenfunctions of conical layers in the small aperture regime. This question is reminiscent of the article [11] where the small angle regime for waveguides with corner is studied. In the latter paper asymptotic expansions at any order for the eigenvalues and eigenfunctions are provided and we would like to determine if similar expansions can be obtained for the conical layer. In fact, in the spirit of the Born-Oppenheimer approximation, one can at least formally reduce the two dimensional waveguide and the conical layer to electric Schrödinger operators in one dimension. The minima of the effective electric potentials determine the behavior of the eigenfunctions. This is a well known fact, for a smooth minimum, that it leads to the study of the so called harmonic approximation (see [9, 12, 33]). However, in [11] and in the present paper, the minima of the effective potentials are not smooth. For the conical layer it involves a logarithmic singularity. That is why we will only be able to provide a finite term in the expansions of the eigenvalues. To do so, we will prove \(a\)\(\text{priori}\) localization estimates for the eigenfunctions, the so called Agmon estimates (see Agmon [2, 3] and, in the semiclassical context, Helffer [20] and Helffer and Sjöstrand [21, 22]). They will imply that the eigenfunctions of the conical layers are localized in the conical cap and, unlike the eigenfunctions of the two dimensional waveguides with corner, get into the rest of the layer at a scale involving the logarithm of the aperture.

### 1.2. The Dirichlet Laplacian on conical layers.

Let us denote by \((x_1, x_2, x_3)\) the Cartesian coordinates of the space \(\mathbb{R}^3\) and by \(0 = (0, 0, 0)\) the origin. The positive Laplace operator is given by \(-\Delta = -\partial^2_1 - \partial^2_2 - \partial^2_3\). We denote by \((r, \phi, z) \in \mathbb{R}_+ \times [0, 2\pi) \times \mathbb{R}\) the cylindrical coordinates with axis \(x_3\), i.e., such that:

\[
1.1 \quad x_1 = r \cos \phi, \quad x_2 = r \sin \phi, \quad \text{and} \quad z = x_3 \in \mathbb{R}.
\]

A conical layer being an axisymmetric domain, it is easier to define it through its \(\text{meridian domain}\). We denote our conical layer by \(\text{Lay}(\theta)\) from its half-opening angle \(\theta \in (0, \frac{\pi}{2})\). The meridian domain of \(\text{Lay}(\theta)\) is denoted by \(\text{Gui}(\theta)\) and defined as, see also Figure 1,

\[
1.2 \quad \text{Gui}(\theta) = \left\{(r, z) \in \mathbb{R}_+ \times \mathbb{R}: \ -\frac{\pi}{\sin \theta} < z, \ \max(0, z \tan \theta) < r < z \tan \theta + \frac{\pi}{\cos \theta} \right\}.
\]
The domains are normalized so that the distance between the two connected components of the boundary of \( \text{Lay}(\theta) \) is \( \pi \) for any value of \( \theta \).

The aim of this paper is to investigate some spectral properties of the Dirichlet Laplacian \(-\Delta_{\text{Lay}(\theta)}\) whose domain is denoted by \( \text{Dom}(-\Delta_{\text{Lay}(\theta)}) \). Note that, according to the value of \( \theta \), this domain is a subspace of \( H^2(\text{Lay}(\theta)) \) (if \( \theta > \theta_0 \)) or not (if \( \theta \leq \theta_0 \)), where \( \theta_0 \) is such that \( P_{1/2}(\cos(\pi - \theta_0)) = 0 \), see [5, §II.4.c] – here \( P_{1/2} \) is the Legendre function with degree \( \nu \), and \( \theta_0 \simeq 0.2738\pi \).

![Figure 1](image_url)

**Figure 1.** The meridian guide \( \text{Gui}(\theta) \).

Through the change of variables (1.1) the Cartesian domain \( \text{Lay}(\theta) \) becomes \( \text{Gui}(\theta) \times S^1 \) and the Dirichlet Laplacian becomes the unbounded selfadjoint operator on \( L^2(\text{Gui}(\theta) \times S^1, rdrd\phi dz) \), denoted by \( \mathcal{H}_{\text{Gui}(\theta) \times S^1} \):

\[
\mathcal{H}_{\text{Gui}(\theta) \times S^1} = -\frac{1}{r}(r\partial_r)^2 - \frac{1}{r^2}\partial^2_\phi - \partial^2_z.
\]

By Fourier series, according to the terminology of [32, §XIII.16], we have the constant fiber sum:

\[
L^2(\text{Gui}(\theta) \times S^1, rdrd\phi dz) = L^2((\text{Gui}(\theta), rdrdz)\otimes L^2(S^1)) = \bigoplus_{m \in \mathbb{Z}} L^2(\text{Gui}(\theta), rdrdz),
\]

where \( L^2(S^1) \) refers to functions on the unit circle with orthonormal basis \( \{e^{2i\pi m\phi}: m \in \mathbb{Z}\} \). The operator \( \mathcal{H}_{\text{Gui}(\theta) \times S^1} \) decomposes as:

\[
\mathcal{H}_{\text{Gui}(\theta) \times S^1} = \bigoplus_{m \in \mathbb{Z}} \mathcal{H}_{\text{Gui}(\theta)}^{[m]}, \quad \text{with} \quad \mathcal{H}_{\text{Gui}(\theta)}^{[m]} = -\frac{1}{r}(r\partial_r)^2 - \partial^2_z + \frac{m^2}{r^2},
\]

where the operators \( \mathcal{H}_{\text{Gui}(\theta)}^{[m]} \) are the fibers of \( \mathcal{H}_{\text{Gui}(\theta) \times S^1} \). The associated quadratic forms are

\[
\mathcal{Q}_{\text{Gui}(\theta)}^{[m]}(\psi) = \int_{\text{Gui}(\theta)} |\partial_r \psi(r, z)|^2 + |\partial_z \psi(r, z)|^2 + \frac{m^2}{r^2} |\psi(r, z)|^2 r dr dz.
\]

The form domains, denoted by \( \text{Dom}(\mathcal{Q}_{\text{Gui}(\theta)}^{[m]}) \), depend on \( m \), namely, cf. [5, §II.3.a],

\[
\text{Dom}(\mathcal{Q}_{\text{Gui}(\theta)}^{[m]}) = \begin{cases} 
\{ \psi: \psi, \partial_r \psi, \partial_z \psi \in L^2(\text{Gui}(\theta), rdrdz), \psi|_{\partial_1 \text{Gui}(\theta)} = 0 \}, & m = 0, \\
\{ \psi: \psi, \partial_r \psi, \partial_z \psi, r^{-1} \psi \in L^2(\text{Gui}(\theta), rdrdz), \psi|_{\partial_1 \text{Gui}(\theta)} = 0 \}, & m \neq 0,
\end{cases}
\]

with \( \partial_1 \text{Gui}(\theta) \) the part of \( \partial \text{Gui}(\theta) \) that does not meet the axis \( r = 0 \). The domain of the operator \( \mathcal{H}_{\text{Gui}(\theta)}^{[m]} \) is deduced from the form domain in the standard way.
1.3. **Main results.** Let us denote by $\mathcal{S}_{\text{disc}}(L)$ and $\mathcal{S}_{\text{ess}}(L)$ the discrete and essential spectrum of the selfadjoint operator $L$, respectively. For our study we start from the following results on the essential and discrete spectrum of $H_{\text{Gui}(\theta)}^{[m]}$ that we deduce from \[16, \S 3\].

**Theorem 1.1** (Exner and Tater \[16\]). Let $\theta \in (0, \frac{\pi}{2})$. There holds,

$$\mathcal{S}_{\text{ess}}(H_{\text{Gui}(\theta)}^{[m]}) = [1, \infty), \quad \forall m \in \mathbb{Z}$$

and

$$\# \mathcal{S}_{\text{disc}}(H_{\text{Gui}(\theta)}^{[0]}) = \infty \quad \text{and} \quad \mathcal{S}_{\text{disc}}(H_{\text{Gui}(\theta)}^{[m]}) = \emptyset \quad \text{if} \ m \neq 0.$$

Note that the minimum at 1 of the essential spectrum is a consequence of the normalization of the meridian guides $\text{Gui}(\theta)$ and that the absence of discrete spectrum when $m \neq 0$ is due to the cancellation of functions in the domain of the operator on the axis $r = 0$.

Relying on this theorem, we see that the investigation of the discrete spectrum of $-\Delta_{\text{Lay}(\theta)}$ reduces to its axisymmetric part $H_{\text{Gui}(\theta)}^{[0]}$. To simplify the notation, we drop the exponent 0, thus denoting this operator by $H_{\text{Gui}(\theta)}$. We denote its eigenvalues by $(\mu_n(\theta))_{n \geq 1}$, ordering them in non-decreasing order and repeating them according to their multiplicity.

We first state a monotonicity result about the dependence on $\theta$ of $\mu_n(\theta)$.

**Proposition 1.2.** For all $n \in \mathbb{N}^*$, the functions $\theta \mapsto \mu_n(\theta)$ are non-decreasing on $(0, \frac{\pi}{2})$ into $\mathbb{R}^+$. 

Before stating our result on the accumulation of these eigenvalues towards the minimum of the essential spectrum, we need to introduce:

**Definition 1.3.** Let $\nu \in \mathbb{R}$ and $L$ be a self-adjoint operator semi-bounded from below and associated with a quadratic form $Q$. We define the counting function $N_\nu(L)$ by:

$$N_\nu(L) = \# \{ \mu \in \mathcal{S}_{\text{disc}}(L) : \mu < \nu \}.$$ 

When working with the quadratic form $Q$ we use the notation $N_\nu(Q)$ instead of $N_\nu(L)$.

In this paper we prove:

**Theorem 1.4.** Let us choose $\theta \in (0, \frac{\pi}{2})$. We have:

$$N_{1-E}(H_{\text{Gui}(\theta)}) \sim \cot \theta \quad \text{as} \quad E \to 0 \quad \frac{\cot \theta}{4\pi} |\ln E|.$$ 

Theorem 1.4 exhibits a logarithmic accumulation of the number of eigenvalues near the threshold of the essential spectrum.

In order to state our result on the spectral asymptotics of the first eigenvalues as $\theta \to 0$ we need to introduce some notations on zeros of Bessel and Airy functions [1].

**Notation 1.5.** Let $J_0$ and $Y_0$ be the 0-th Bessel functions of first and second kind, respectively. For all $n \geq 1$, the $n$-th zero (in increasing order) of $J_0$ is denoted by $j_{0,n}$. Let $Ai$ be the Airy function of first kind and $A$ be its reverse function $A(z) = Ai(-z)$. For all $n \geq 1$, we denote by $z_A(n)$ the $n$-th zero (in increasing order) of $A$. 

The following theorem describes the behavior of the first eigenvalues of $H_{\text{Gui}(\theta)}$ in the limit $\theta \to 0$. This result confirms that $\mu_n(\theta)$ goes to $\frac{j_{0,1}^2}{\pi^2}$ as $\theta$ goes to 0 which is conjectured in [16, Figure 2].

**Theorem 1.6.** For all $n \in \mathbb{N}$, we have the asymptotic expansion:

$$
\mu_n(\theta) = \frac{j_{0,1}^2}{\pi^2} + \frac{(2j_{0,1})^{2/3}}{\pi^2} z_A(n) \theta^{2/3} + O(\theta |\ln \theta|^{3/2}), \quad n = 1, \ldots, N_0.
$$

In Section 2 we prove Proposition 1.2 by reformulating the problem in another domain. Section 3 deals with Theorem 1.4. We prove that counting the eigenvalues on the meridian waveguide $\text{Gui}(\theta)$ reduces to consider operators on a half-strip, leading to count the eigenvalues of one-dimensional operators. Section 4 concerns the small aperture regime $\theta \to 0$. First, we show that the problem admits a semiclassical formulation. Then, we use Agmon localization estimates to obtain Theorem 1.6. Finally in Appendix A we illustrate the main results of this paper by numerical computations by finite element method.

### 2. Monotonicity of the Eigenvalues

We denote by $Q_{\text{Gui}(\theta)}$ the quadratic form associated with $H_{\text{Gui}(\theta)}$ and by Dom($Q_{\text{Gui}(\theta)}$) its domain. For the proof of Proposition 1.2 and further use, we consider the change of variables (rotation):

$$
(2.1) \quad s = z \cos \theta + r \sin \theta, \quad u = -z \sin \theta + r \cos \theta,
$$

that transforms the meridian guide $\text{Gui}(\theta)$ into the strip with corner $\Omega(\theta)$ (see Figure 2), defined by:

$$
\Omega(\theta) = \{(s, u) \in \mathbb{R}^2 : s \geq -\pi \cot \theta, \ \max(0, -s \tan \theta) < u < \pi\}.
$$

For $\psi \in \text{Dom}(Q_{\text{Gui}(\theta)})$, we set $\tilde{\psi}(s, u) = \psi(r, z)$ and we have the identity $Q_{\text{Gui}(\theta)}(\psi) = Q_{\Omega(\theta)}(\tilde{\psi})$ with the new quadratic form

$$
(2.2) \quad Q_{\Omega(\theta)}(\tilde{\psi}) = \int_{\Omega(\theta)} (|\partial_s \tilde{\psi}|^2 + |\partial_u \tilde{\psi}|^2) (s \sin \theta + u \cos \theta) \, du \, ds.
$$

The proof of the monotonicity of the eigenvalues $\mu_n(\theta)$ now follows the same track that the analogous proof in [10, §3] for the case of broken waveguides. To avoid the dependence on $\theta$ of the domain $Q_{\Omega(\theta)}$ we perform the change of variables $(s, u) \mapsto (\hat{s}, \hat{u}) = (s \tan \theta, u)$ that transforms

![Figure 2. The domain $\Omega(\theta)$.](image-url)
the domain $\Omega(\theta)$ into $\Omega := \Omega(\frac{\pi}{2})$. Setting $\tilde{\psi}(s, \hat{u}) = \tilde{\psi}(s, u)$ we get for the Rayleigh quotients:

$$\frac{Q_{\text{Gui}}(\theta)(\psi)}{\|\psi\|^2} = \frac{\int_{\Omega}(\tan^2 \theta|\partial_s \tilde{\psi}|^2 + |\partial_u \tilde{\psi}|^2)(s + \hat{u}) \cos \theta \cot \theta ds d\hat{u}}{\int_{\Omega} |\tilde{\psi}|^2 (s + \hat{u}) \cos \theta \cot \theta ds d\hat{u}}$$

$$= \frac{\int_{\Omega}(\tan^2 \theta|\partial_s \tilde{\psi}|^2 + |\partial_u \tilde{\psi}|^2)(s + \hat{u}) ds d\hat{u}}{\int_{\Omega} |\tilde{\psi}|^2 (s + \hat{u}) ds d\hat{u}},$$

that appear to be nondecreasing functions of $\theta$. The result follows from the min-max formulas for the eigenvalues.

3. Counting the eigenvalues

In this section we prove Theorem 1.4. The idea is to reduce to a one-dimensional operator.

We will need a result adapted from Kirsch and Simon [24], later extended by Hassel and Marshall in [19]. Let $c > 0$, we are interested in the Friedrichs extension of the following quadratic form,

$$q(\varphi) = \int_{1}^{+\infty} |\partial_x \varphi|^2 - \frac{c}{x^2} |\varphi|^2 \, dx, \quad \varphi \in C^\infty_0(1, +\infty).$$

and we denote by $\mathfrak{h}$ the corresponding operator.

**Theorem 3.1 (Kirsch and Simon [24])**. Let $V_0 \in C^\infty_0(1, +\infty)$. If $c > \frac{1}{4}$, there holds:

$$\mathcal{N}_{-E}(h + V_0) \sim_{E \to 0} \frac{1}{2\pi} \sqrt{c - \frac{1}{4} |\ln E|}.$$

In § 3.1 we find a lower bound for $\mathcal{N}_{1-E}(Q_{\text{Gui}}(\theta))$. An upper bound is obtained in § 3.2 and these bounds, together with Theorem 3.1, yield Theorem 1.4 in § 3.3.

For the next two subsections, instead of working with the quadratic form $Q_{\text{Gui}}(\theta)$, it will be more convenient to use the quadratic form $Q_{\Omega}(\theta)$ introduced in (2.2).

3.1. A lower bound on the number of bound states. Let us denote by $\Sigma$ the half-strip $(1, +\infty) \times (0, \pi)$. We consider the quadratic form $Q_{\Sigma}(\theta)$, Friedrichs extension of the form defined for all functions $\psi \in C^\infty_0(\Sigma)$ by:

$$Q_{\Sigma}(\theta)(\psi) = \int_{\Sigma} \left(|\partial_s \psi|^2 + |\partial_u \psi|^2\right) (s \sin \theta + u \cos \theta) \, ds du,$$

where the $(s, u)$ variables are related to the physical domain through the change of variables (2.1).

We also define the one-dimensional quadratic form $\hat{q}(\theta)$, Friedrichs extension of the form defined, for all $\hat{\varphi} \in C^\infty_0(1, +\infty)$, by:

$$\hat{q}(\theta)(\hat{\varphi}) = \int_{1}^{+\infty} |\partial_\sigma \hat{\varphi}|^2 - \frac{1}{4\sigma^2 \sin^2 \theta} |\hat{\varphi}|^2 \, d\sigma.$$

**Proposition 3.2.** Let us fix $\theta \in (0, \frac{\pi}{2})$. Let $E > 0$, and set $\hat{E} = (1 + \pi \cot \theta)^2 E$. We have:

$$\mathcal{N}_{-E}(\hat{q}(\theta)) \leq \mathcal{N}_{1-E}(Q_{\Omega}(\theta)).$$
Proof. Any \( \psi \in \text{Dom}(Q_{\Sigma}(\theta)) \) can be extended by zero, defining \( \psi_0 \in \text{Dom}(Q_{\Omega(\theta)}) \) such that \( Q_{\Sigma}(\theta)(\psi) = Q_{\Omega}(\theta)(\psi_0) \). The min-max principle then yields

\[
(3.2) \quad \mathcal{N}_{1-E}(Q_{\Sigma}(\theta)) \leq \mathcal{N}_{1-E}(Q_{\Omega(\theta)}).
\]

For \( \psi \in \text{Dom}(Q_{\Sigma}(\theta)) \), let \( \hat{\psi}(s, u) = \sqrt{s \sin \theta + u \cos \theta} \psi(s, u) \). We have:

\[
(3.3) \quad Q_{\Sigma}(\theta)(\psi) = \int_{\Sigma} |\partial_s \hat{\psi}|^2 + |\partial_u \hat{\psi}|^2 - \frac{1}{4(s \sin \theta + u \cos \theta)^2} |\hat{\psi}|^2 \, ds \, du
\]

and we bound \( (s \sin \theta + u \cos \theta)^2 \) from above by \( (s \sin \theta + \pi \cos \theta)^2 \), obtaining

\[
(3.4) \quad Q_{\Sigma}(\theta)(\psi) \leq \int_{\Sigma} |\partial_s \hat{\psi}|^2 + |\partial_u \hat{\psi}|^2 - \frac{1}{4(s \sin \theta + \pi \cos \theta)^2} |\hat{\psi}|^2 \, ds \, du.
\]

Now, we denote by \( q(\theta) \) the quadratic form, Friedrichs extension of the form defined for \( \varphi \in \mathcal{C}_0^\infty (1, +\infty) \), by:

\[
q(\theta)(\varphi) = \int_1^{+\infty} |\partial_s \varphi|^2 - \frac{1}{4(s \sin \theta + \pi \cos \theta)^2} |\varphi|^2 \, ds.
\]

So the right hand side of (3.4) has two blocs with separated variables: The first one is \( q(\theta) \) in \( s \) variable and the second one is the Dirichlet Laplacian quadratic form on \( H_0^1(0, \pi) \) whose eigenvalues are \( k^2 \), for \( k \geq 1 \) integer. We deduce

\[
(3.5) \quad \mathcal{N}_{-E}(q(\theta)) \leq \mathcal{N}_{1-E}(Q_{\Sigma}(\theta)).
\]

Let us perform the change of variables \( \sigma = \frac{s + \pi \cot \theta}{1 + \pi \cot \theta} \). For all function \( \varphi \) in the domain \( \text{Dom}(q(\theta)) \), we denote \( \hat{\varphi}(\sigma) = \varphi(s) \). We get:

\[
\frac{q(\theta)(\varphi)}{\int_1^{+\infty} |\varphi|^2 \, ds} = (1 + \pi \cot \theta)^{-2} \frac{\hat{q}(\theta)(\hat{\varphi})}{\int_1^{+\infty} |\hat{\varphi}|^2 \, ds}.
\]

Using (3.2), (3.5) and the min-max principle, this achieves the proof of Proposition 3.2. \( \square \)

3.2. An upper bound on the number of bound states. To obtain an upper bound, we follow the strategy of [29] and [10, § 5]. Let \( (\chi_0, \chi_1) \) be a \( \mathcal{C}^\infty \) partition of unity such that:

\[
\chi_0(s)^2 + \chi_1(s)^2 = 1,
\]

with \( \chi_0(s) = 1 \) for \( s < 1 \) and \( \chi_0(s) = 0 \) for \( s > 2 \). We set \( W(s) = |\chi_0'(s)|^2 + |\chi_1'(s)|^2 \). Now, we consider the quadratic form \( \hat{q}(\theta) \), Friedrichs extension of the form defined for all \( \hat{\varphi} \in \mathcal{C}_0^\infty (1, +\infty) \):

\[
\hat{q}(\theta)(\hat{\varphi}) = \int_1^{+\infty} |\partial_s \hat{\varphi}|^2 - \left( \frac{1}{4s^2 \sin^2 \theta} + W(s) \right) |\hat{\varphi}|^2 \, ds.
\]

Proposition 3.3. Let us choose \( \theta \in (0, \frac{\pi}{2}) \). There exists a constant \( C(\theta) \) (depending only on \( \theta \)), such that for all \( E > 0 \), we have:

\[
\mathcal{N}_{1-E}(Q_{\Omega(\theta)}) \leq C(\theta) + \mathcal{N}_{-E}(\hat{q}(\theta)).
\]
Proof. For any function \( \psi \in \operatorname{Dom}(Q_{\Omega(\theta)}) \), we deduce from the definition of \( W(s) \) and from the “IMS” formula (see [9]):

\[
(3.6) \quad \mathcal{Q}_{\Omega(\theta)}(\psi) = \mathcal{Q}_{\Omega(\theta)}(\chi_0 \psi) + \mathcal{Q}_{\Omega(\theta)}(\chi_1 \psi) - \int_{\Omega(\theta)} W(s)|\chi_0 \tilde{\psi}|^2 + |\chi_1 \tilde{\psi}|^2 \left( s \sin \theta + u \cos \theta \right) \, du ds.
\]

We introduce the subdomains \( \Sigma_0 = \{(s, u) \in \Omega(\theta) : s < 2\} \) and \( \Sigma_1 = \Sigma \) of \( \Omega(\theta) \). Then we consider the quadratic forms \( \mathcal{Q}_{\Sigma_0} \) and \( \mathcal{Q}_{\Sigma_1} \) defined for \( \phi \in \operatorname{Dom}(Q_{\Sigma_j}) \) by:

\[
\mathcal{Q}_{\Sigma_j}(\phi) = \int_{\Sigma_j} (|\partial_s \psi|^2 + |\partial_u \psi|^2 - W(s)|\phi|^2) \left( s \sin \theta + u \cos \theta \right) \, du ds, \quad j = 0, 1,
\]

where the form domains are defined by

\[
\operatorname{Dom}(Q_{\Sigma_0}) = \{ \phi \in \operatorname{Dom}(Q_{\Omega(\theta)}) : \phi = 0 \text{ on } [2, \infty) \times (0, \pi) \},
\]

\[
\operatorname{Dom}(Q_{\Sigma_1}) = \{ \phi \in \operatorname{Dom}(Q_{\Omega(\theta)}) : \phi = 0 \text{ on } (-\infty, 1] \times (0, \pi) \}.
\]

Of course, those quantities also depend on \( \theta \). As we are looking for a result for a chosen \( \theta \), we have dropped the mention of \( \theta \) in these notations. Thanks to (3.6), we get:

\[
\mathcal{Q}_{\Omega(\theta)}(\psi) = \mathcal{Q}_{\Sigma_0}(\chi_0 \psi) + \mathcal{Q}_{\Sigma_1}(\chi_1 \psi).
\]

Using [10, Lemma 5.2] we find

\[
(3.7) \quad \mathcal{N}_{1-E}(Q_{\Omega(\theta)}) \leq \mathcal{N}_{1-E}(Q_{\Sigma_0}) + \mathcal{N}_{1-E}(Q_{\Sigma_1}).
\]

We now provide upper bounds for both terms of the right hand side of inequality (3.7).

1) We have, obviously: \( \mathcal{N}_{1-E}(Q_{\Sigma_0}) \leq \mathcal{N}_1(Q_{\Sigma_0}) \) for all \( E > 0 \). Then we note that

\[
\int_{\Sigma_0} (|\partial_s \psi|^2 + |\partial_u \psi|^2) \left( s \sin \theta + u \cos \theta \right) \, du ds - \|W\|_{\infty} \|\psi\|^2_{\Sigma_0} \leq \mathcal{Q}_{\Sigma_0}(\psi).
\]

The quadratic form on the left hand side is associated with the axisymmetric Dirichlet Laplacian in a bounded domain. This operator has a compact resolvent and its eigenvalue sequence tends to infinity. We deduce

\[
(3.8) \quad \mathcal{N}_{1-E}(Q_{\Sigma_0}) \leq \mathcal{N}_1(Q_{\Sigma_0}) = C(\theta) < \infty.
\]

2) For \( \psi \in \operatorname{Dom}(Q_{\Sigma_1}) \), we set \( \hat{\psi}(s, u) = \sqrt{s} \sin \theta + u \cos \theta \psi(s, u) \) and we find (see (3.3)):

\[
\int_{\Sigma_1} (|\partial_s \hat{\psi}|^2 + |\partial_u \hat{\psi}|^2 - \frac{1}{4s^2 \sin^2 \theta} |\hat{\psi}|^2 - W(s)|\hat{\psi}|^2) \, du ds \leq \mathcal{Q}_{\Sigma_1}(\psi).
\]

Separating the variables, we obtain:

\[
(3.9) \quad \mathcal{N}_{1-E}(Q_{\Sigma_1(\theta)}) \leq \mathcal{N}_{-E}(\hat{\psi}(\theta)).
\]

Now, we can end the proof of Proposition 3.3: With estimates (3.8) and (3.9), we obtain an upper bound for the left hand side of inequality (3.7). This yields Proposition 3.3. \( \square \)
3.3. Proof of Theorem 1.4. Thanks to Propositions 3.2 and 3.3 we have the following inequality:

\[
N_{-(1+\pi \cot \theta)^2} E(\tilde{q}(\theta)) \leq N_{1-E}(\Omega(\theta)) \leq C(\theta) + N_{-E}(\tilde{q}(\theta)).
\]

Now we use Theorem 3.1 on each side of (3.10). For the left hand side, we obtain:

\[
N_{-(1+\pi \cot \theta)^2} E(\tilde{q}(\theta)) \sim \frac{\cot \theta}{4\pi} |\ln \left( (1 + \pi \cot \theta)^2 E \right)| \sim \frac{\cot \theta}{4\pi} |\ln E|.
\]

On the right hand side, because \( W \in C_0^\infty(1, +\infty) \) we get:

\[
N_{-E}(\tilde{q}(\theta)) \sim \frac{\cot \theta}{4\pi} |\ln(E)|.
\]

Together with (3.10), it gives Theorem 1.4. 

\[\Box\]

4. Conical Layers in the Small Aperture Limit

This section is devoted to the proof of Theorem 1.6. We work with the meridian guide \( \Gamma_i(\theta) \) and the operator \( H_{\Gamma_i}(\theta) \) introduced in Subsection 1.2. \( \Gamma_i(\theta) \) depends on \( \theta \) and it is more convenient to transfer its dependence into the coefficients of the operator. Therefore, we perform the change of variable:

\[
x = z\sqrt{2} \sin \theta, \quad y = r\sqrt{2} \cos \theta.
\]

The meridian guide \( \Gamma_i(\theta) \) becomes \( \Gamma_i = \Gamma_i(\frac{\pi}{4}) \) and \( H_{\Gamma_i}(\theta) \) is unitary equivalent to

\[
D_{\Gamma_i}(\theta) = -2 \sin^2 \theta \partial_x^2 - 2 \cos^2 \theta \frac{1}{y} \partial_y (y \partial_y).
\]

Let \( h = \tan \theta \), dividing by \( 2 \cos^2 \theta \) we obtain the partially semiclassical operator in the \( x \)-variable:

\[
L_{\Gamma_i}(h) = -h^2 \partial_x^2 - \frac{1}{y} \partial_y (y \partial_y).
\]

This operator acts on \( L^2(\Gamma_i, ydx dy) \) and its eigenvalues, denoted by \( (\lambda_n(h))_{n \geq 1} \) satisfy:

\[
\lambda_n(\tan \theta) = (2 \cos^2 \theta)^{-1} \mu_n(\theta).
\]

By definition, the regime \( \theta \to 0 \) corresponds to the semiclassical regime \( h \to 0 \). We will prove Theorem 1.6 using the scaled operator \( L_{\Gamma_i}(h) \).

Besides, we introduce some notations and results that are useful in this section. We define \( \mathrm{Tri} \), the triangular end of \( \Gamma_i \), by:

\[
\mathrm{Tri} = \{(x, y) \in \Gamma_i : x < 0\}.
\]

We consider the operator \( L_{\mathrm{Tri}}(h) \) defined by:

\[
L_{\mathrm{Tri}}(h) = -h^2 \partial_x^2 - \frac{1}{y} \partial_y (y \partial_y),
\]

with domain \( \text{Dom}(L_{\mathrm{Tri}}(h)) = \{\psi \in \text{Dom}(L_{\Gamma_i}(h)) : \psi(0, \cdot) = 0, \text{supp } \psi \subset \mathrm{Tri}\} \). In fact, \( L_{\mathrm{Tri}}(h) \) is associated with the 0-th fiber of the Dirichlet Laplacian in a cone. In [31, Proposition 9], one of the authors studies the eigenpairs of cones of small aperture:
Theorem 4.1. The eigenvalues of $\mathcal{L}_{\text{Tri}}(h)$, denoted by $\lambda_n^\Delta(h)$, admit the expansions:

$$
\lambda_n^\Delta(h) \sim \sum_{k \geq 0} \beta_{k,n} h^{k/3}, \quad \text{with } \beta_{0,n} = \frac{j_{0,1}^2}{2\pi^2}, \beta_{1,n} = 0, \beta_{2,n} = \frac{(2j_{0,1}^2)^{2/3}}{2\pi^2} z_A(n).
$$

Here $\sim_{h \to 0}$ means that for all $K \in \mathbb{N}$, there exist $C_K > 0$ and $h_0 > 0$ such that for all $h \in (0, h_0)$ we have: $|\lambda_n^\Delta(h) - \sum_{k=0}^K \beta_{k,n} h^{k/3}| \leq C_K h^{(K+1)/3}$.

This section is divided into three parts. In Section 4.1 we study a one dimensional operator with electric potential $v$, the so-called Born-Oppenheimer approximation of $\mathcal{L}_{\text{Gui}}(h)$. Since this reduced operator is a lower bound of $\mathcal{L}_{\text{Gui}}(h)$ and thanks to the confining properties of $v$, we deduce, in Section 4.2, that the eigenfunctions of $\mathcal{L}_{\text{Gui}}(h)$ are essentially localized in Tri. In Section 4.3, we infer that the two-terms semiclassical expansions of the eigenvalues of $\mathcal{L}_{\text{Gui}}(h)$ and $\mathcal{L}_{\text{Tri}}(h)$ coincide.

4.1. Effective one dimensional operator. As the operator $\mathcal{L}_{\text{Gui}}(h)$ is partially semiclassical, we may use the strategy of the famous Born-Oppenheimer approximation (see [6, 8, 23, 25, 27, 28]). Let us denote by $v(x)$ the first eigenvalue of the operator, acting on $L^2((\max(0, x), x + \pi \sqrt{2}), ydy)$ and defined by $h_x = -\frac{1}{y} \partial_y(y \partial_y)$ with Dirichlet conditions in $y = x + \pi \sqrt{2}$ and in $y = x$ if $x > 0$.

Since we are concerned with the expansion of the low lying eigenvalues, this approximation consists in replacing $-\frac{1}{y} \partial_y(y \partial_y)$ in the expression of $\mathcal{L}_{\text{Gui}}(h)$ by $v(x)$ on each slide of Gui at fixed $x$.

Thus we consider the following one dimensional Schrödinger operator, acting on $L^2(-\pi \sqrt{2}, +\infty)$,

$$
-\hbar^2 \partial_x^2 + v(x).
$$

Let us now describe the function $v$. For each $x > -\pi \sqrt{2}$, we consider the quadratic form $q^\text{trans}_x$ associated with the transverse operator $-\frac{1}{y} \partial_y(y \partial_y)$

$$
q^\text{trans}_x(\varphi) = \int_{\max(0,x)}^{x+\pi \sqrt{2}} |\partial_y \varphi|^2 ydy.
$$

with Dirichlet boundary conditions in $y = x + \pi \sqrt{2}$ and in $y = x$ if $x > 0$. Let $\text{Dom}(q^\text{trans}_x)$ denote its form domain. Then

$$
v(x) = \min_{\varphi \in \text{Dom}(q^\text{trans}_x)} \frac{q^\text{trans}_x(\varphi)}{\int_{\max(0,x)}^{x+\pi \sqrt{2}} |\varphi|^2 \sqrt{2y} dy}.
$$

For $x \in (-\pi \sqrt{2}, 0)$, we have the explicit expression (first eigenvalue of the Dirichlet problem on the disk of radius $x + \pi \sqrt{2}$, cf. [31, §3.3]):

$$
v(x) = \frac{j_{0,1}^2}{(x + \pi \sqrt{2})^2}.
$$

Proposition 4.2. The effective potential $v$ has the following properties:

(i) $v$ is continuous and decreasing on $(-\pi \sqrt{2}, 0]$, continuous and non-decreasing on $(0, \infty)$.

(ii) The infimum of $v$ on $(-\pi \sqrt{2}, \infty)$ is positive.
(iii) For all $x > 0$, we have:

$$\frac{1}{2} - \frac{1}{4x^2} \leq v(x) \leq \frac{1}{2}.$$  

(iv) The effective potential $v$ is continuous at 0:

$$v(0) = \frac{\bar{J}_0^2}{2\pi^2} \quad \text{and} \quad v(x) - \frac{\bar{J}_0^2}{2\pi^2} \sim \frac{1}{\ln x} \frac{j_{0,1} Y_{0}(j_{0,1})}{2\pi |J'_{0}(j_{0,1})|},$$

where $J_0$ and $Y_0$ are the Bessel functions of first and second kind, respectively.

So $v$ is continuous on $(-\pi\sqrt{2}, \infty)$ and attains its (unique) minimum at $x = 0$, see Figure 3.

Proof. (i) The statement for $x \leq 0$ is an obvious consequence of the expression (4.3) of $v$. To tackle the case $x > 0$, we perform the change of variables $\hat{y} = y - x$ that transforms the quadratic form $q^\text{trans}_x$ into

$$\int_0^{\pi\sqrt{2}} |\partial_y \varphi(\hat{y} + x)|^2 (\hat{y} + x) \, d\hat{y}.$$  

To get rid of the metrics, we use the change of function defined by

$$\hat{\varphi} = \sqrt{\hat{y} + x} \varphi(\hat{y} + x).$$

It transforms the quadratic form $q^\text{trans}_x$ into $q^\text{trans}_{\hat{y}}$ defined by:

$$\hat{q}^\text{trans}_{x}(\hat{\varphi}) = \int_0^{\pi\sqrt{2}} |\partial_{\hat{y}} \hat{\varphi}|^2 - \frac{1}{4(\hat{y} + x)^2} |\hat{\varphi}|^2 \, d\hat{y},$$

so that we have the identities

$$q^\text{trans}_x(\varphi) = \hat{q}^\text{trans}_{\hat{y}}(\hat{\varphi}) \quad \text{and} \quad \int_x^{x+\pi\sqrt{2}} |\varphi|^2 \, dy = \int_0^{\pi\sqrt{2}} |\hat{\varphi}|^2 \, d\hat{y}.$$
For any positive $x$, the domain of the form $\tilde{q}_x^\text{trans}$ is $H^1_0(0, \pi \sqrt{2})$. At this point it becomes obvious that for any $\tilde{\phi} \in H^1_0(0, \pi \sqrt{2})$ the Rayleigh quotients $\tilde{q}_x^\text{trans}(\tilde{\phi})\|\tilde{\phi}\|^{-2}$ are non-decreasing functions of $x$, hence the corresponding monotonicity of $v$ on $(0, \infty)$.

(iii) For $a \in [0, \pi \sqrt{2})$, let us introduce the operator $\tilde{h}_a = -y^{-1} \partial_y y \partial_y$, acting on $L^2\left((a, \pi \sqrt{2}), ydy\right)$ with Dirichlet conditions at $a$ and $\pi \sqrt{2}$, and denote by $v(a)$ its lowest eigenvalue, which is a non decreasing function of $a$. We note that $v(0)$ is larger than the first eigenvalue $j_{0,1}^2/2\pi^2$ of the Dirichlet Laplacian on the disc of radius $\pi \sqrt{2}$. By dilation, we get that

$$v(x) = \frac{2\pi^2}{(x + \pi \sqrt{2})^2} \tilde{v}\left(\frac{x \pi \sqrt{2}}{x + \pi \sqrt{2}}\right) \geq \frac{2\pi^2}{(x + \pi \sqrt{2})^2} \frac{j_{0,1}^2}{2\pi^2}.$$ 

Combining this with (i), we obtain (ii).

(iv) Let $x > 0$. The equation on eigenpairs $(\lambda, \phi)$ of $h_x$ can be written as

$$y^2 \partial_y^2 \varphi + y \partial_y \varphi + \lambda y^2 \varphi = 0,$$

$$\varphi(x) = 0 \quad \text{and} \quad \varphi(x + \pi \sqrt{2}) = 0.$$ 

The first equation is a Bessel type equation whose general solution can be written as

$$AJ_0(\lambda^{1/2}y) + BY_0(\lambda^{1/2}y), \quad A, B \in \mathbb{R}.$$ 

Finding a non-zero solution to (4.4)-(4.5) is equivalent to find a non-zero couple $(A, B)$ such that the above function satisfies both Dirichlet boundary conditions at $x$ and $x + \sqrt{2}$. An equivalent condition is that the following determinant is zero:

$$\left| \begin{array}{cc} J_0(\lambda^{1/2}x) & Y_0(\lambda^{1/2}x) \\ J_0(\lambda^{1/2}(x + \pi \sqrt{2})) & Y_0(\lambda^{1/2}(x + \pi \sqrt{2})) \end{array} \right| = 0.$$ 

So, the effective potential $v$ satisfies the implicit equation:

$$J_0(v(x)^{1/2}x) Y_0(v(x)^{1/2}(x + \pi \sqrt{2})) = J_0(v(x)^{1/2}(x + \pi \sqrt{2})) Y_0(v(x)^{1/2}x).$$

We know that the effective potential $v$ is bounded from above on $(0, \infty)$ by (iii) and is bounded from below by $j_{0,1}^2/2\pi^2$ by (ii). Hence, we deduce:

$$v(x)^{1/2}x \rightarrow 0 \quad \text{and} \quad v(x)^{1/2}(x + \pi \sqrt{2}) \rightarrow \alpha \geq j_{0,1}.$$ 

Since the left hand side of (4.6) is bounded and $Y_0(x) \rightarrow -\infty$ we get:

$$J_0(v(x)^{1/2}(x + \pi \sqrt{2})) \rightarrow 0.$$
Taking the limit in the left hand side of (4.8), the only possible accumulation points of \( \{v(x)\} \) as \( x \to 0_+ \) are \( \frac{j_{2p}^2}{2\pi^2} \) \( (p \in \mathbb{N}^*) \). Because for all \( p \geq 2, \frac{j_{2p}^2}{2\pi^2} \geq \frac{1}{2} \), thanks to (ii) we get the continuity of the effective potential in \( x = 0 \). The \( J_0 \) zeros are simple, thus \( J'_0(j_{0,1}) \neq 0 \). We obtain:

\[
J_0(v(x)^{1/2}(x + \pi \sqrt{2})) \sim_{x \to 0^+} (v(x)^{1/2}(x + \pi \sqrt{2}) - j_{0,1}) J'(j_{0,1}),
\]

\[
(4.9)
\]

\[
Y_0(v(x)^{1/2}) \sim_{x \to 0^+} \frac{2}{\pi} \ln \left( \frac{1}{2} v(x)^{1/2} \right) \sim_{x \to 0^+} \frac{2}{\pi} \ln x.
\]

Moreover, we have:

\[
(4.10) \quad J_0(v(x)^{1/2}) \xrightarrow[x \to 0^+]{} 1 \quad \text{and} \quad Y_0(v(x)^{1/2}(x + \pi \sqrt{2})) \xrightarrow[x \to 0^+]{} Y_0(j_{0,1}).
\]

Equations (4.6), (4.9) and (4.10) yield:

\[
\frac{2}{\pi} \ln x \sim_{x \to 0^+} \frac{Y_0(j_{0,1})}{\sqrt{2\pi^2 v(x) - j_{0,1}}} J_0'(j_{0,1}).
\]

This provides the proof of the asymptotic equivalence of \( v - \frac{j_{0,1}^2}{2\pi^2} \) with \( \frac{1}{\ln x} \frac{j_{0,1} Y_0(j_{0,1})}{J_0(j_{0,1})} \). The positivity of the quotient \( \frac{1}{\ln x} \frac{Y_0(j_{0,1})}{J_0(j_{0,1})} \) is then a consequence of (i) \( v \) non-decreasing on \( (0, \infty) \). \( \square \)

Here, we are not going to investigate the spectrum of the one dimensional operator defined in (4.2), nevertheless one can see that the logarithmic behavior of \( v \) near \( x = 0^+ \) prevents us from using the classical harmonic approximation.

### 4.2. Agmon localization estimates

Before stating and proving Agmon localization estimates, we remark that for \( N_0 \in \mathbb{N}^* \), there exists \( \Gamma_0 > 0 \) and \( h_0 > 0 \) such that for all \( n \in \{1, \ldots, N_0\} \) and all \( h \in (0, h_0) \):

\[
(4.11) \quad \left| \lambda_n(h) - \frac{j_{0,1}^2}{2\pi^2} \right| \leq \Gamma_0 h^{2/3}.
\]

To obtain inequality (4.11), we first observe that \( \lambda_n(h) - \frac{j_{0,1}^2}{2\pi^2} \geq 0 \). This comes from the following fact: If we denote by \( Q(h) \) the quadratic form associated with the operator \( \mathcal{L}_{\text{Gui}}(h) \), for all \( \psi \) in the form domain \( \text{Dom}(Q(h)) \) we have:

\[
(4.12) \quad Q(h)(\psi) = \int_{\text{Gui}} h^2 |\partial_x \psi|^2 + |\partial_y \psi|^2 ydydx \geq \int_{\text{Gui}} h^2 |\partial_x \psi|^2 + v(x) |\psi|^2 ydydx \geq \frac{j_{0,1}^2}{2\pi^2} \|\psi\|^2.
\]

The min-max principle yields \( \lambda_n(h) - \frac{j_{0,1}^2}{2\pi^2} \geq 0 \). Since \( \text{Tri} \subset \text{Gui} \), by Dirichlet bracketing we get:

\[
(4.13) \quad \lambda_n(h) \leq \lambda_n^\Delta(h).
\]

Now, by Theorem 4.1, we know that \( |\lambda_n^\Delta(h) - \frac{j_{0,1}^2}{2\pi^2}| \leq \Gamma_0 h^{2/3} \), which gives inequality (4.11).

As a consequence of Proposition 4.2 (iv), there exists \( x_1 > 0 \) such that

\[
(4.14) \quad \forall x \in [0, x_1], \quad v(x) \geq \frac{j_{0,1}^2}{2\pi^2} + \frac{c_0}{|\ln x|} \quad \text{with} \quad c_0 = \frac{j_{0,1}}{4\pi} \frac{|Y_0(j_{0,1})|}{|J_0'(j_{0,1})|}.
\]
We set
\[ G_1 = \text{Gui} \cap \{(x, y) : x \in (0, x_1)\} \quad \text{and} \quad G_2 = \text{Gui} \cap \{(x, y) : x \in (x_1, \infty)\}. \]

Our estimates of Agmon type are as follows.

**Proposition 4.3.** Let \( \Gamma_0 > 0 \), there exist \( h_0, C_0 > 0 \) and \( \eta_1, \eta_2, \eta_3 > 0 \) such that for all \( h \in (0, h_0) \) and all eigenpair \((\lambda, \psi)\) of \( \mathcal{L}_{\text{Gui}}(h) \) satisfying \(|\lambda - \frac{j_0^2}{2\pi^2}| \leq \Gamma_0 h^{2/3}\), we have:

\[
\int_{\text{Gui}} e^{2\Phi/h}(|\psi|^2 + |h\partial_x \psi|^2) \, dx dy \leq C_0 \|\psi\|^2,
\]

with the Lipschitz weight function \( \Phi \) defined on \( \text{Gui} \) by
\[
\Phi(x, y) = \begin{cases} 
\Phi_0(x) = \eta_0 |x|^{3/2} & \text{if } \pi \sqrt{2} < x < 0, \text{ i.e. } (x, y) \in \text{Tri} \\
\Phi_1(x) = \eta_1 \int_0^x \frac{1}{\sqrt{|\ln t|}} dt, & \text{if } 0 < x < x_1 \text{ i.e. } (x, y) \in G_1 \\
\Phi_2(x) = \eta_2 (x - x_1) + \Phi_1(x_1) & \text{if } x_1 < x \text{ i.e. } (x, y) \in G_2.
\end{cases}
\]

Thanks to these estimates we understand the localization scales of the eigenfunctions of \( \mathcal{L}_{\text{Gui}}(h) \). In the triangular end \( \text{Tri} \), they are localized at a scale \( h^{2/3} \) near \( x = 0 \) whereas they get into the layer at a scale \( h \sqrt{|\ln h|} \). This is different from the two dimensional waveguides with corner where the eigenfunctions visit the guiding part at a scale \( h \). In [11], the effective potential obtained has a jump at \( x = 0 \), then is constant. Here it is different: The logarithmic behavior of \( v \) at \( x = 0^+ \) allows the eigenfunctions to leak a little more outside the triangular end.

**Proof.** For \( \Phi \) a Lipschitz function only depending on the variable \( x \in (-\pi \sqrt{2}, +\infty) \), we have the formula of "IMS" type:

\[
\int_{\text{Gui}} \left| h^2 \partial_x (e^{\Phi/h} \psi) \right|^2 + \left| e^{\Phi/h} \partial_y \psi \right|^2 - (\lambda + \Phi'(x)^2) |e^{\Phi/h} \psi|^2 \right) \, dx dy = 0.
\]

Now, thanks to the first inequality in (4.12) we deduce:

\[
\int_{\text{Gui}} \left( h^2 |\partial_x (e^{\Phi/h} \psi)|^2 + (v(x) - \lambda - \Phi'(x)^2) |e^{\Phi/h} \psi|^2 \right) \, dx dy \leq 0.
\]

By convexity of \( v \) in \((-\pi \sqrt{2}, 0)\) and inequality (4.14) we get:

\[
\int_{\text{Gui}} h^2 |\partial_x (e^{\Phi/h} \psi)|^2 \, dx dy + I_{\text{Tri}} + I_{G_1} + I_{G_2} \leq 0,
\]

with
\[
I_{\text{Tri}} = \int_{\text{Tri}} \left( \frac{j_0^2}{2\pi^2} + \frac{j_0^2}{(\pi \sqrt{2})^2} |x| - \lambda - \Phi'(x)^2 \right) |e^{\Phi/h} \psi|^2 \, dx dy,
\]
\[
I_{G_1} = \int_{G_1} \left( \frac{j_0^2}{2\pi^2} + \frac{c_0}{|\ln x|} - \lambda - \Phi'(x)^2 \right) |e^{\Phi/h} \psi|^2 \, dx dy,
\]
\[
I_{G_2} = \int_{G_2} (v(x_1) - \lambda - \Phi'(x)^2) |e^{\Phi/h} \psi|^2 \, dx dy.
\]
Then, using $\lambda = \frac{j_{0,1}^2}{2\pi^2} \leq \Gamma_0 h^{2/3}$, this becomes:

\begin{equation}
\int_{\text{Gui}} h^2 |\partial_x (e^{\Phi/h} \psi)|^2 \, y \, dx \, dy + \hat{I}_{\text{Tri}} + \hat{I}_{G_1} + \hat{I}_{G_2} \leq 0,
\end{equation}

with

\begin{align*}
\hat{I}_{\text{Tri}} &= \int_{\text{Tri}} \left( \frac{j_{0,1}^2}{(\pi \sqrt{2})^2} |x| - \Gamma_0 h^{2/3} - \Phi'(x)^2 \right) |e^{\Phi/h} \psi|^2 \, y \, dx \, dy, \\
\hat{I}_{G_1} &= \int_{G_1} \left( \frac{c_0}{|\ln x|} - \Gamma_0 h^{2/3} - \Phi'(x)^2 \right) |e^{\Phi/h} \psi|^2 \, y \, dx \, dy, \\
\hat{I}_{G_2} &= \int_{G_2} \left( v(x) - \frac{j_{0,1}^2}{2\pi^2} - \Gamma_0 h^{2/3} - \Phi'(x)^2 \right) |e^{\Phi/h} \psi|^2 \, y \, dx \, dy,
\end{align*}

We are led to take:

\begin{align*}
\Phi(x, y) &= \Phi_0(x) \mathbf{1}_{(-\pi, 0)}(x) + \Phi_1(x) \mathbf{1}_{(0, 1)}(x) + \Phi_2(x) \mathbf{1}_{(1, +\infty)}(x),
\end{align*}

where $\Phi_0$, $\Phi_1$, and $\Phi_2$ are defined by (4.16) for some positive constants $\eta_0$, $\eta_1$, and $\eta_2$. For $\eta_0$, $\eta_1$, and $\eta_2$ small enough, there exist positive $\hat{\eta}_0$, $\hat{\eta}_1$, and $\hat{\eta}_2$ such that:

\begin{align*}
\hat{I}_{\text{Tri}} &= \int_{\text{Tri}} (\hat{\eta}_0 |x| - \Gamma_0 h^{2/3}) |e^{\Phi/h} \psi|^2 \, y \, dx \, dy, \\
\hat{I}_{G_1} &= \int_{G_1} (\hat{\eta}_1 |\ln x|^{-1} - \Gamma_0 h^{2/3}) |e^{\Phi/h} \psi|^2 \, y \, dx \, dy, \\
\hat{I}_{G_2} &= \int_{G_2} (\hat{\eta}_2 - \Gamma_0 h^{2/3}) |e^{\Phi/h} \psi|^2 \, y \, dx \, dy.
\end{align*}

Note that, if $h$ is small, we may find a positive constant $\gamma_2$ such that $\hat{I}_{G_2} \geq \gamma_2 \int_{G_2} |e^{\Phi/h} \psi|^2 \, y \, dx \, dy$. Let $\varepsilon > 0$ be a chosen positive number. We define the $h$-dependent subdomains:

\begin{align*}
\text{Tri}^{\text{far}} &= \{(x, y) \in \text{Tri}, \, \hat{\eta}_0 |x| - \Gamma_0 h^{2/3} \geq \varepsilon h^{2/3}\}, \\
G_1^{\text{far}} &= \{(x, y) \in G_1, \, \frac{\hat{\eta}_1}{|\ln x|} - \Gamma_0 h^{2/3} \geq \varepsilon h^{2/3}\}, \\
\text{Tri}^{\text{near}} &= \{(x, y) \in \text{Tri}, \, \hat{\eta}_0 |x| - \Gamma_0 h^{2/3} \leq \varepsilon h^{2/3}\}, \\
G_1^{\text{near}} &= \{(x, y) \in G_1, \, \frac{\hat{\eta}_1}{|\ln x|} - \Gamma_0 h^{2/3} \leq \varepsilon h^{2/3}\},
\end{align*}

Then, we split the integrals in (4.17) and we obtain:

\begin{equation}
\Gamma_0 h^{2/3} \left( \int_{\text{Tri}^{\text{near}}} |e^{\Phi_1/h} \psi|^2 \, y \, dx \, dy + \int_{G_1^{\text{near}}} |e^{\Phi_1/h} \psi|^2 \, y \, dx \, dy \right) \geq \int_{\text{Gui}} h^2 |\partial_y (e^{\Phi/h} \psi)|^2 \, y \, dx \, dy \\
+ \varepsilon h^{2/3} \int_{\text{Tri}^{\text{far}}} |e^{\Phi_1/h} \psi|^2 \, y \, dx \, dy + \varepsilon h^{2/3} \int_{G_1^{\text{far}}} |e^{\Phi_1/h} \psi|^2 \, y \, dx \, dy + \hat{I}_{G_2}.
\end{equation}

Set $\gamma_1 := (\varepsilon + \Gamma_0)/\hat{\eta}_1$. In $\text{Tri}^{\text{near}}$ there holds $-h^{2/3} \gamma_1 < x < 0$. Thus we find

\[ \frac{\Phi_0(x)}{h} \leq \eta_1 \gamma_1^{3/2}. \]

Set $\gamma_2 := (\varepsilon + \Gamma_0)/\hat{\eta}_2$. In $G_1^{\text{near}}$, we have $|\ln x|^{-1/2} \leq h^{1/3} \sqrt{\gamma_2}$ and $0 < x < e^{-h^{2/3} \gamma_2^{-1}}$. Thus

\[ \frac{\Phi_2(x)}{h} \leq \eta_2 x h^{1/3} \sqrt{\gamma_2} \frac{1}{h} \leq \eta_2 e^{-h^{2/3} \gamma_2^{-1}} h^{-2/3} \sqrt{\gamma_2}. \]
We deduce that $\Phi / h$ is bounded independently on $h$ on $\text{Tri}^{\text{near}} \cup \text{Q}_1^{\text{near}}$. Now, the Agmon-type estimate (4.15) is a consequence of inequality (4.18).

4.3. **Proof of Theorem 1.6.** Let $N_0 \in \mathbb{N}^*$. We consider the $N_0$ first eigenvalues of $\mathcal{L}_{\text{Gui}}(h)$. In each eigenspace associated with $\lambda_n(h)$ we choose a normalized eigenfunction $\psi_{n,h}$ so that $\langle \psi_{n,h}, \psi_{p,h} \rangle = 0$ if $n \neq p$. Moreover, if $\mathcal{B}(h)$ (resp. $\mathcal{Q}(h)$) denotes the bilinear (resp. quadratic) form associated with $\mathcal{L}_{\text{Gui}}(h)$, for $n \neq p$ we also have $\mathcal{B}(h)(\psi_{n,h}, \psi_{p,h}) = 0$ and $\mathcal{Q}(h)(\psi_{n,h}) = \lambda_n(h)\|\psi_{n,h}\|^2$.

Let $a \geq 2$, we introduce a smooth cut-off function $\chi$ defined for $x > 0$ and satisfying:

$$\chi(x) = 1, \text{ if } x \leq a \quad \text{and} \quad \chi(x) = 0, \text{ if } x \geq 2a.$$  

We define the cut-off function $\chi_h$ at the scale $h|\ln h|^{3/2}$ by $\chi_h(x) = \chi(x h^{-1} |\ln h|^{-3/2})$ (for all $x > 0$). The “IMS” formula yields

$$\mathcal{Q}(h)(\chi_h \psi_{n,h}) = \lambda_n(h)\|\chi_h \psi_{n,h}\|^2 + R(h),$$  

where the commutator term $R(h)$ is given by

$$R(h) = \frac{1}{|\ln h|^3} \int_{\Gamma_{\text{Gui}}} |\chi'(x h^{-1} |\ln h|^{-3/2})|^2 \|\psi_{n,h}\|^2 y \, dxdy.$$  

With the weight function $\Phi$ defined by (4.16) we obtain, thanks to the estimate (4.15):

$$R(h) \leq |\ln h|^{-3} \|\chi'\|_{L^\infty(-\pi \sqrt{2}, \infty)} \int_{\Gamma_{\text{Gui}} \cap \{(x,y) : a \leq xh^{-1} |\ln h|^{-3/2} \leq 2a\}} e^{2\Phi/h} e^{-2\Phi/h} \|\psi_{n,h}\|^2 y \, dxdy$$

$$\leq C |\ln h|^{-3} e^{-2\Phi(ah/\ln h^{3/2})/h} \|\psi_{n,h}\|^2.$$  

Thanks to the lower bound on the weight function, we get, for $h$ small enough,

$$2\Phi(ah|\ln h|^{3/2}) \geq 2\eta_1 \int_{ah/2}^{ah|\ln h|^{3/2}} \frac{1}{\sqrt{|\ln (ah/2)|}} \, dt \geq \eta_1 ah |\ln h|^{3/2} \ln (ah/2) |^{-1/2},$$  

and, using that $a \geq 2$, we find

$$2\Phi(ah|\ln h|^{3/2})/h \geq \eta_1 a |\ln h| = -\eta_1 a \ln h.$$

Now we choose $a = \max\{2, 2/\eta_1\}$ and find $e^{-2\Phi(ah|\ln h|^{3/2})/h} \leq e^{2\ln h} = h^2$. Thus we deduce:

(4.19)

$$R(h) \leq C h^2.$$  

Similarly the functions $\chi_h \psi_{n,h}$ are almost orthogonal for the bilinear form $\mathcal{B}(h)$ in the sense that there holds, for $n \neq p$:

$$|\mathcal{B}(h)(\chi_h \psi_{n,h}, \chi_h \psi_{p,h})| \leq C h^2.$$  

We introduce

$$S_{N_0}(h) = \text{vect}(\chi_h \psi_{1,h}, \ldots, \chi_h \psi_{N_0,h}).$$  

and we get

(4.20)$$\forall \psi_h \in S_{N_0}(h), \quad \mathcal{Q}(h)(\psi_h) \leq (\lambda_{N_0}(h) + C h^2)\|\psi_h\|^2.$$  

Now, we define the triangle $\text{Tri}(h)$ by its vertices

$$(-\pi \sqrt{2}, 0), \quad (h|\ln h|^{3/2}, 0), \quad \text{and} \quad (h|\ln h|^{3/2}, h|\ln h|^{3/2} + \pi \sqrt{2}),$$
and consider the operator $L_{\text{Tri}(h)} := -h^2 \partial_x^2 - \frac{1}{y} \partial_y (y \partial_y)$ on $\text{Tri}(h)$ with Dirichlet condition on the two sides of $\text{Tri}(h)$ that are not contained in the axis $r = 0$. Since $\text{Tri}(h)$ can be obtained by a dilation of ratio $1 + \frac{h |\ln(h)|^{3/2}}{\pi \sqrt{2}}$ from $\text{Tri}$, we find that the eigenvalues of $L_{\text{Tri}(h)}$ are equal to

$$\left(1 + \frac{h |\ln(h)|^{3/2}}{\pi \sqrt{2}}\right)^{-2} \lambda_n^\Delta(h).$$

We can extend the elements of $\mathcal{S}_{N_0}(h)$ by zero so that $Q(h)(\psi_h) = Q_{\text{Tri}(h)}(h)(\psi_h)$ for $\psi_h \in \mathcal{S}_{N_0}(h)$. Using (4.20) and the min-max principle, we get, for all $n \in \{1, \ldots N_0\}$,

$$\left(1 + \frac{h |\ln(h)|^{3/2}}{\pi \sqrt{2}}\right)^{-2} \lambda_n^\Delta(h) \leq \lambda_n(h) + Ch^2.$$

Together with (4.13) and Theorem 4.1 this implies Theorem 1.6. \hfill $\Box$

**Appendix A. Numerical Results**

![Figure 4. First 6 eigenvalues $\mu_n(\theta)$ ($n = 1, \ldots, 6$) vs $\theta$ (in degrees). The black dot is the value $j_{0,1}^2/\pi^2$. Mesh with 1616 triangles and #DOF = 30325.](image)

We illustrate properties satisfied by the eigenvalues and eigenfunctions through numerical simulations. The computations are performed with the operator $D_{\text{Gui}}(\theta)$ defined in (4.1). The integration domain has to be finite: We truncate the domain $\text{Gui}$ sufficiently far away from the origin. We use the finite element library Méлина++ [26] with interpolation degree 6 and a quadrature rule of degree 13. The elements are triangles and the different meshes and the number of DOF (degrees of freedom) are mentioned in legends.
Figure 4 shows the six first eigenvalues as functions of $\theta$. The monotonicity of eigenvalues, their accumulation below the threshold of the essential spectrum, and their convergence to $j_{0,1}/\pi^2$ as $\theta \to 0$ can be observed.

We computed the first 12 eigenvalues for $\theta = 5^\circ$ and first 8 for $\theta = 8^\circ$. We are interested in $E_j(\theta) = 1 - \mu_j(\theta)$ because, by definition, for all $E \in [E_{j+1}(\theta), E_j(\theta))$ we have $\mathcal{N}_{1-E}(\mathcal{H}_{Gui}(\theta)) = \mathcal{N}_{1-E}(\mathcal{D}_{Gui}(\theta)) = j$. The jumps occur at $E = E_j(\theta)$. In Figure 5, we plot the quantity $\mathcal{N}_{1-E}(\mathcal{H}_{Gui}(\theta))$ as function of $\ln_{10} E$, compared with the asymptotics of Theorem 1.4.

Finally, in Figure 6 we depict the first eigenfunctions for small $\theta$. This is the same numerical computations as in [16, Figure 3] and it enlightens the Agmon localization estimates of Proposition
4.3: The eigenfunctions penetrate into the meridian guide Gui(θ) and, unlike the two dimensional broken waveguides, are not only localized in the triangular end of the meridian guide.
